

## Computer controlled reflecting-light microscopy

The early examination of benign oder malignant skin alterations often comes together with some problems and even experienced medicals have their difficulties. The digital incident light microscopy (patented method with polarised light) provides a new view on skin morphology.

As one can see through the upper skin layers, deeper underlying structures become visible. ***Who knows when a birthmark alters!?***

The medic archives the recorded images and is able to notice changes in size and color. Security for the patient to detect melanoms early is guaranteed.
